Along-Track Interferometric SAR (AT-InSAR)

Shuttle Radar Topography Mission (SRTM) (DLR / ASI, 2000)

- Two SAR antennas acquire images with short time lag
 - Phase difference \propto Doppler shift \propto line-of-sight velocity
- Velocity measurements at SAR resolution

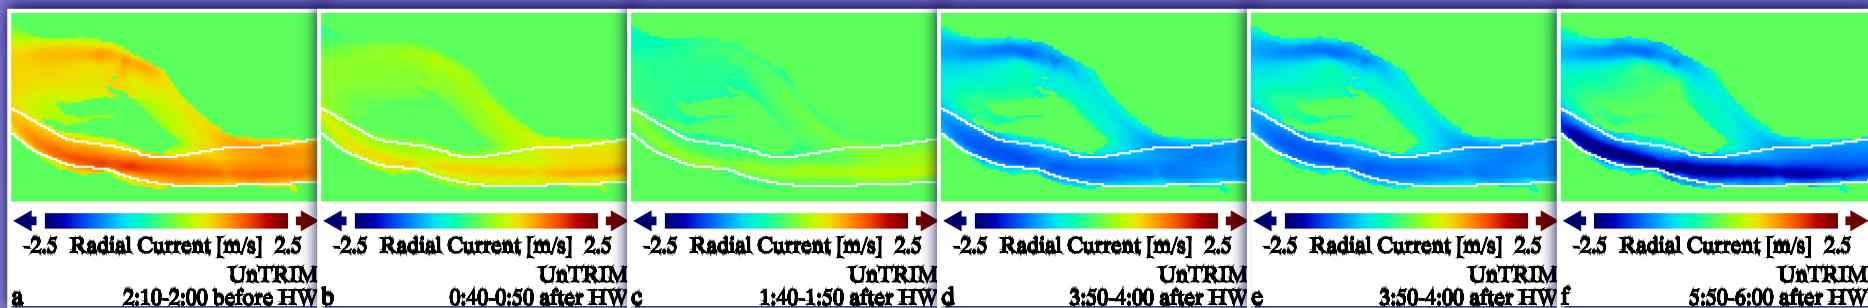

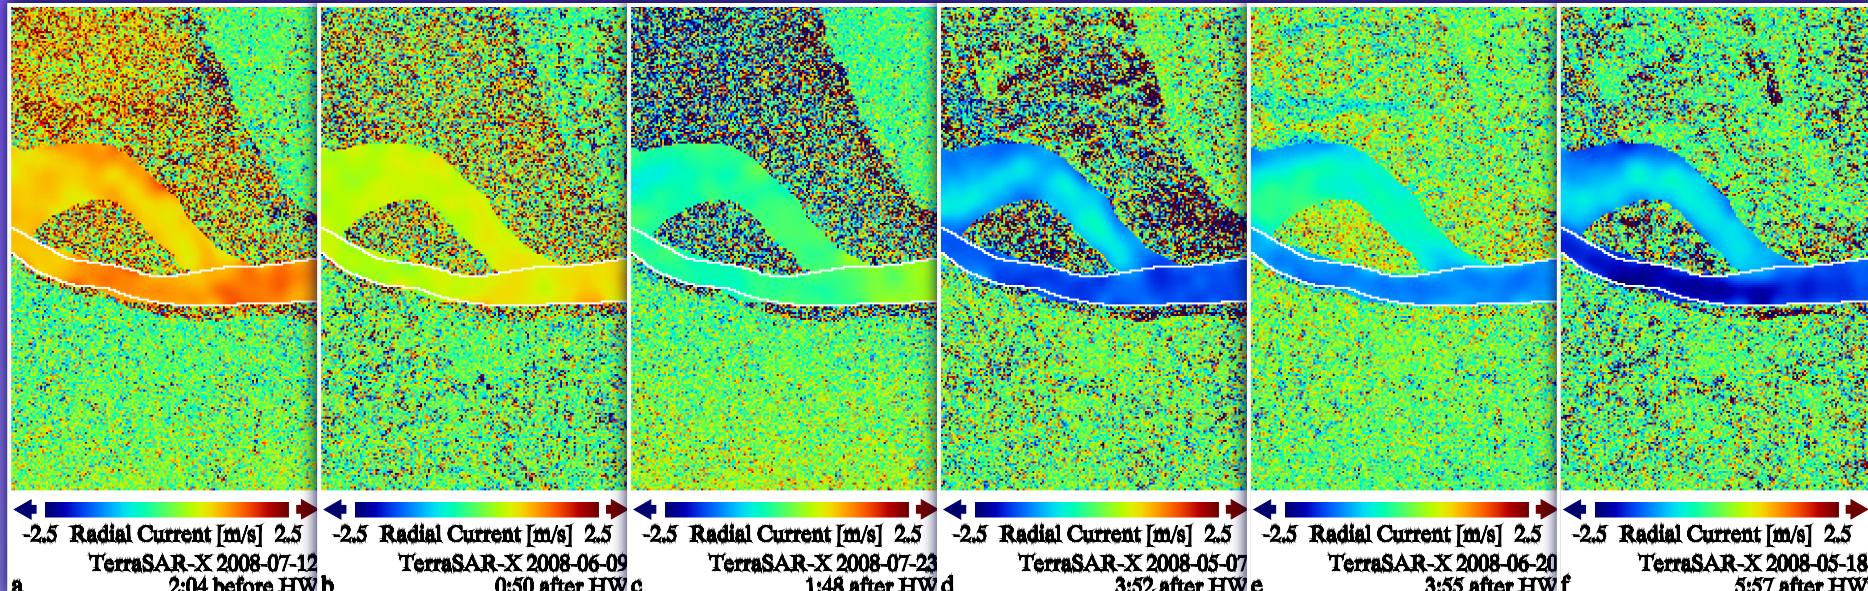

- State-of-the-art satellite receiving station operated by U Miami
- Direct access to most existing SAR satellites
- Beginning to acquire & process TerraSAR-X along-track InSAR images quasi-operational in spring 2012

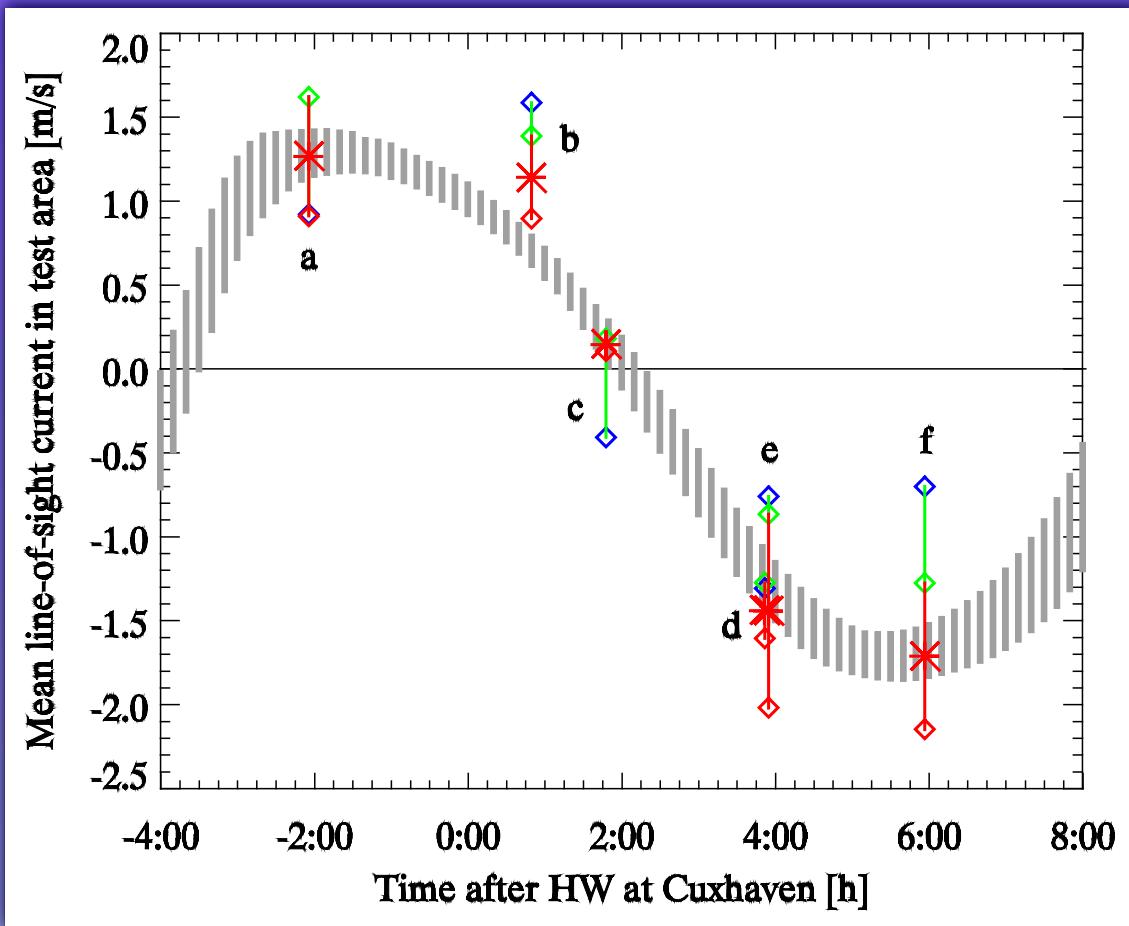

TerraSAR-X Example: Elbe River, Germany

Aperture Switching mode, test area size = 16 km × 25 km

- Six overpasses at different tidal phases
- Noise filtering & wave motion corrections applied
- Good agreement with numerical Elbe model

Quantitative Analysis of Elbe Results

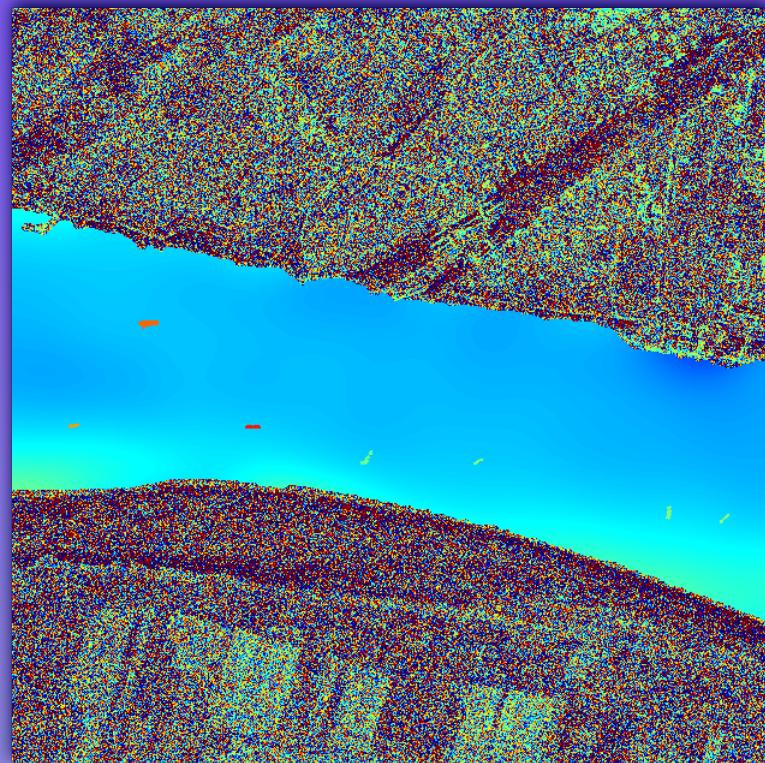

- | Range of tidal currents according to numerical model
- ◊ Doppler velocities from TerraSAR-X
- ◆ Large-scale trend removed
- ◇ 100% theoretical correction applied
- * 50% theoretical correction applied

Another TerraSAR-X / Elbe River Example

Dual Receive Antenna mode, test area size = $6.3 \text{ km} \times 6.3 \text{ km}$

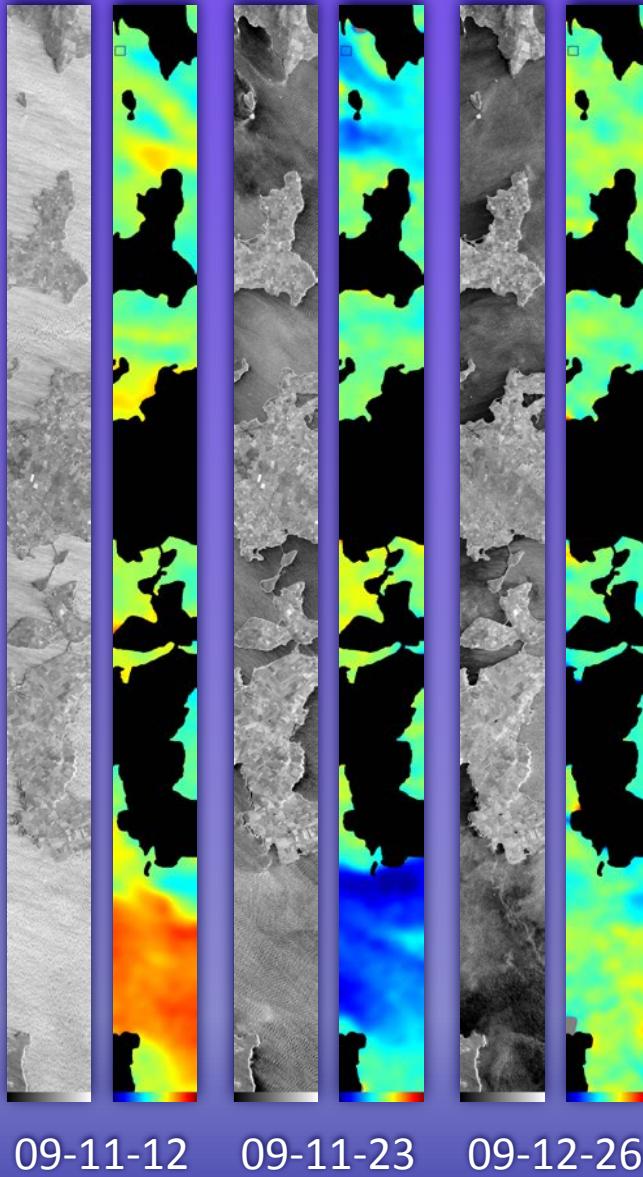

May 05, 2009

Current -2.5 m/s  $+2.5 \text{ m/s}$
Ships -7.5 m/s  $+7.5 \text{ m/s}$

- Test: High bandwidth, high PRF – original pixel size = $0.82 \text{ m} \times 1.17 \text{ m}$
- Eff. baseline $\approx 1.1 \text{ m}$ (AS mode: typically 0.8 m)
- Better quality than AS mode, limited availability

Hydropower Test Site: Orkney Islands

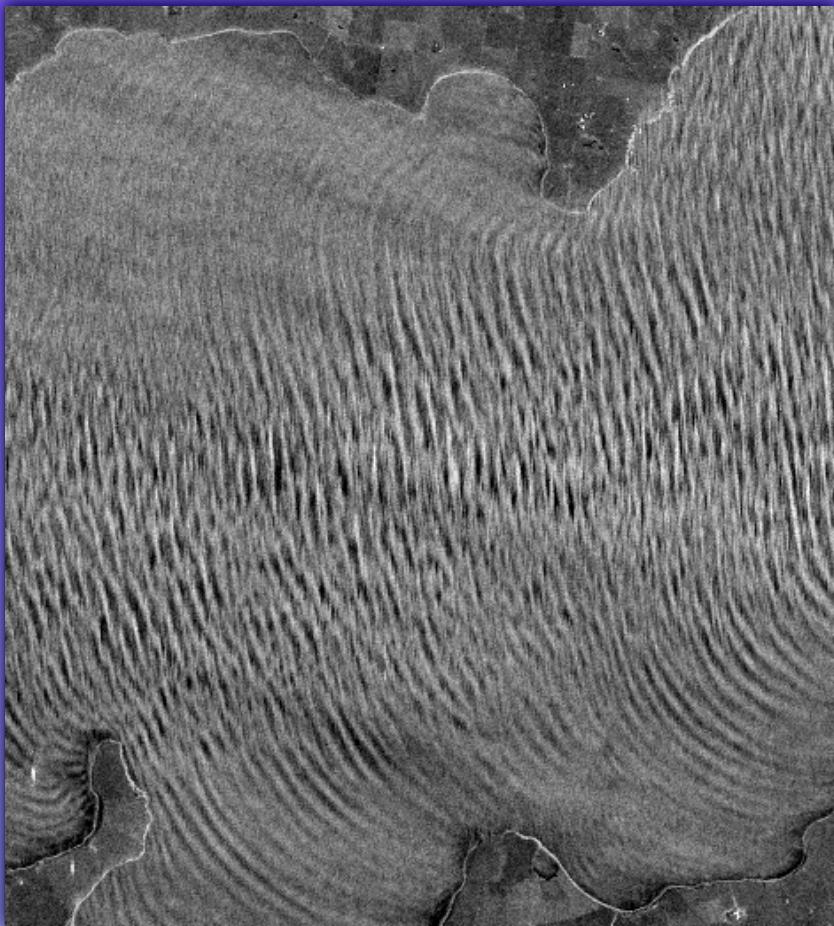

- Strong tidal currents, hydropower test area
- Acquired several long scenes in AS mode, high bandwidth
- Pixel size = $0.87 \text{ m} \times 2.13 \text{ m}$, coverage $\approx 4.6 \text{ km} \times 65.0 \text{ km}$
- Applied wave correction = $+1.04, -0.70, +0.66 \text{ m/s}$
- Mean residual current at coast = $+0.23, -0.04, -0.04 \text{ m/s}$
- Pretty good preliminary results; more detailed analysis to come

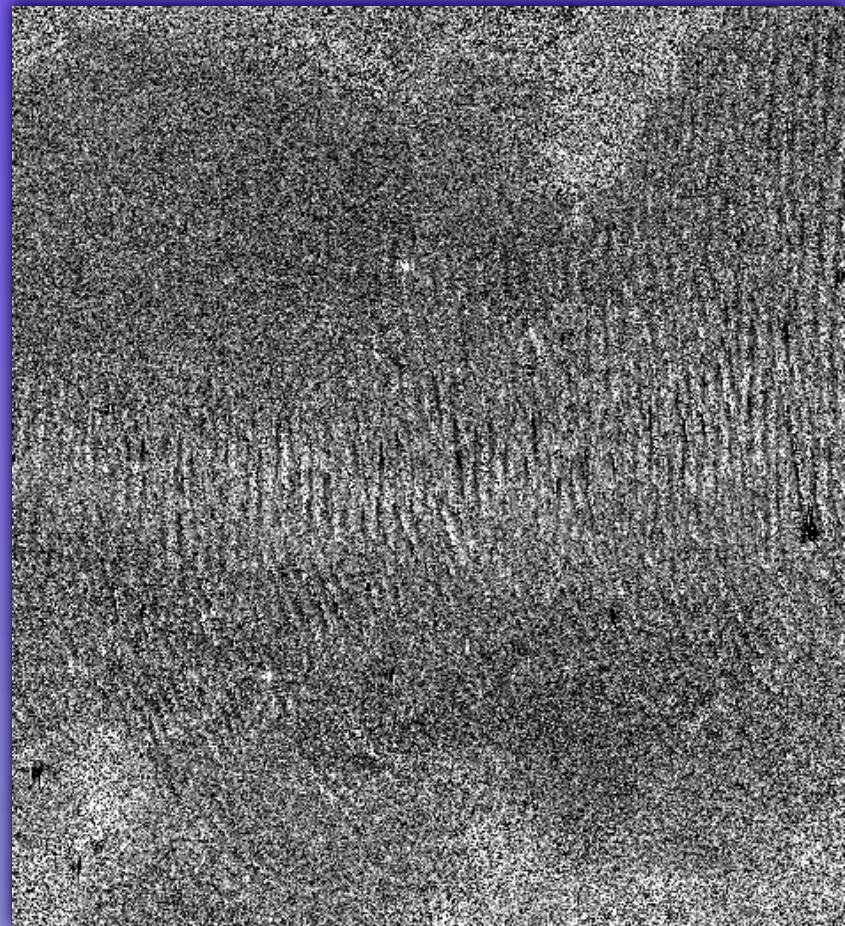

Orkney Detail

Averaged over about $10\text{ m} \times 10\text{ m}$ cells, $4.7\text{ km} \times 5.2\text{ km}$

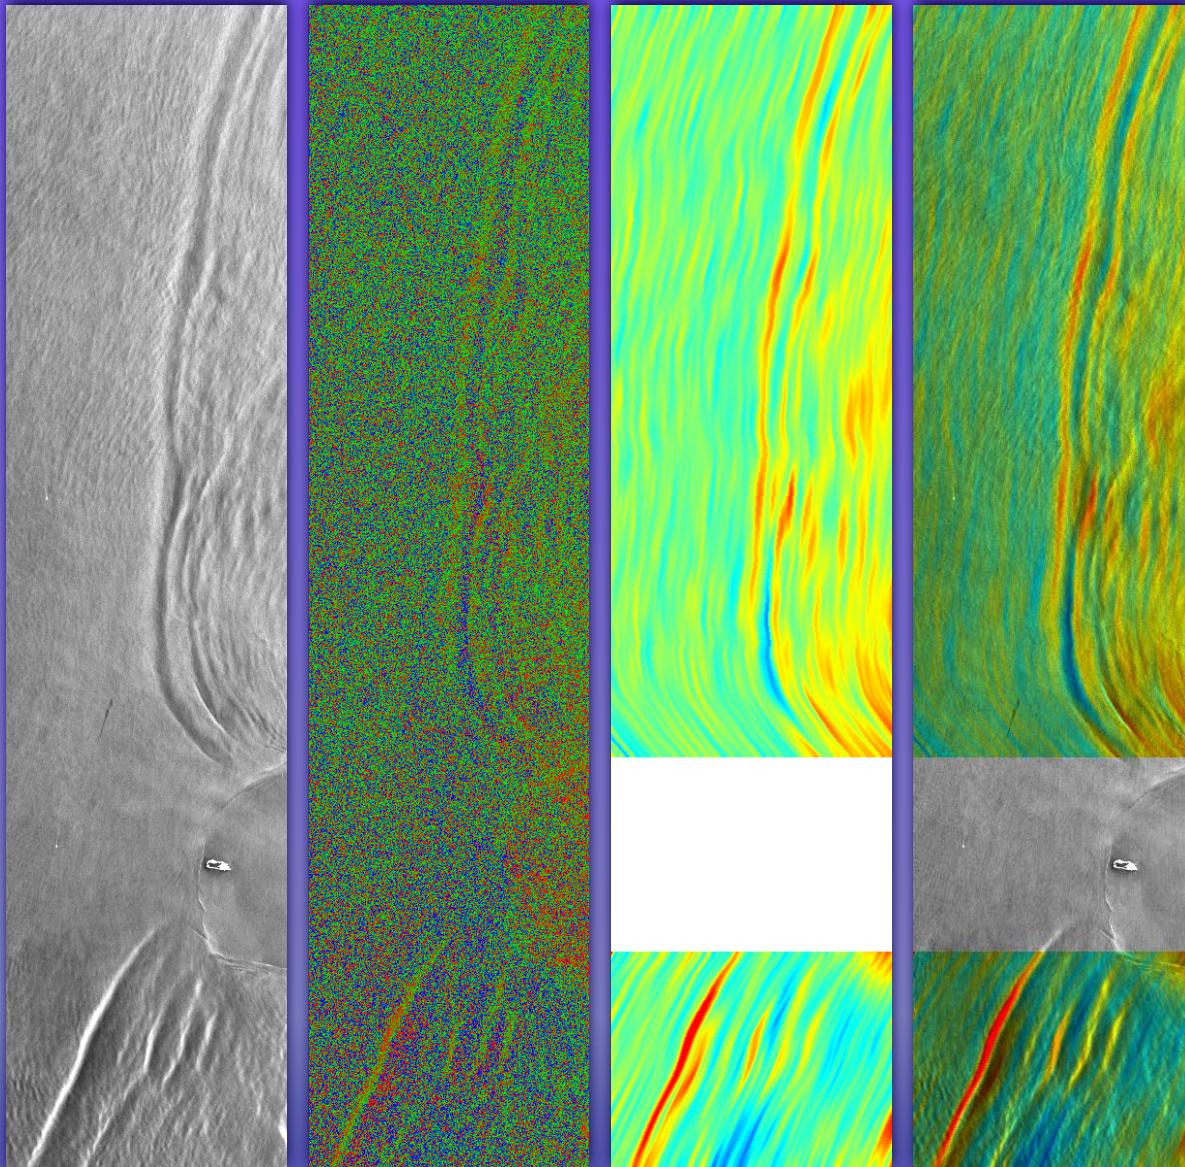

Intensity image

Phase image

Oceanography: Internal Waves at Dongsha

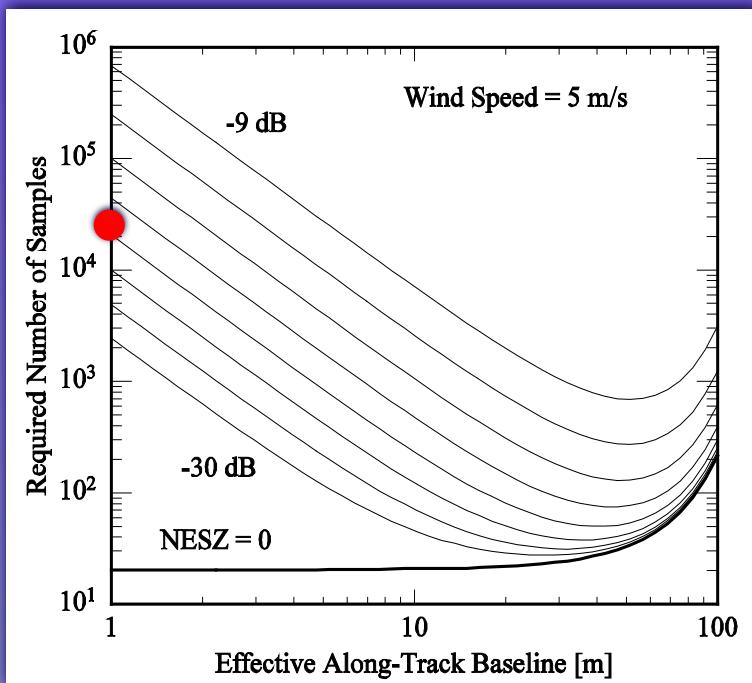

- DRA Mode campaign, April 22, 2010
- Scene coverage $\approx 29 \text{ km} \times 120 \text{ km}$
- Phase image filtered parallel to leading int. soliton signature
- Clear correlation of intensity & velocity
- Velocities consistent with expectations

Possible Performance Improvements

- Phase noise (and spatial resolution) can be reduced by averaging
- Short baseline: Poor phase sensitivity, instrument noise issues
- Long baseline: Poor coherence (decorrelation of signal)

● TerraSAR-X, 1515 pixels per $100 \text{ m} \times 100 \text{ m}$

Number of independent samples to be averaged for 0.1 m/s accuracy

→ Accuracy / resolution can be improved by factor 10 with more favorable instrument parameters

Summary

- Along-track interferometric SAR technique permits high-resolution surface current measurements from satellites
- Currently possible with TerraSAR-X, but suboptimal parameters
- Theoretical limits: 0.1 m/s accuracy at approx. 100 m resolution
- Promising applications
 - Current measurements in rivers
 - Coastal engineering (e.g. siting of hydropower turbines)
 - Oceanography (e.g. internal waves)
